Summary

The UN/ECE international co-operative programme of effects on materials is an international project that has been running for eight years at 39 test sites in 14 countries from 1987 to 1995. A second phase of the project started in 1997 with an adjusted number of test sites and countries participating. In the second phase 30 test sites and 19 countries participated. During the interim period 1995 to 1997 trend analysis for metal corrosion and exposure of the two materials glass and polymer continued. Norwegian Institute for Air Research has been a sub-centre and responsible for the environmental data storing, reporting and evaluation during the whole programme.

This report primarily presents the data for the period 1998 to 1999 of environmental measurements obtained in the ECE-ICP on materials programme. However, also the environmental data for the period 1997 to 1998 is included, since more data have been reported to the sub-centre after the last report was finalised. Only the test sites that are included in the second phase of the programme are included in this report. The exposure in most countries started late in October or in November in 1997, and the yearly average values have therefore been calculated from November to October. The monthly values for the two years are reported in Appendix B.

An evaluation of the regularity and quality of the total data base shows that sites belonging to the EMEP net of sites or to national surveillance programmes have the best regularity.

To obtain a good database for dose-response evaluation, it is important to have a wide range in the data for the most important parameters. The data obtained so far indicates that we have a good spread in the data for all important gases as well as for the most important meteorological data.

Earlier comparisons of the yearly values have shown that the SO₂ concentration has been reduced for almost all sites. The trend is that the concentration reduction has been 75% for the total database during the period 1987–1995. For NO₂ a reduction is also observed, mainly in the highest polluted areas. For the NO₂ data as a whole, a reduction of 40% can be seen. For O₃ no trend is observed. In this report scatterplots comparing the two years 1997-98 and 1998-99 have been made. No specific trend is observed for any of the gases except for site 43, where the first year had a mean value for SO₂ of 35 µg/m³ while the second year had 60.3 µg/m³.

International Co-operative Programme on Materials, including Historic and Cultural Monuments

Environmental data report November 1998 to October 1999

1 Introduction

Airborne acidifying pollutants are known to be one major cause of corrosion of different materials including the extensive damage that has been observed on historic and cultural monuments. In order to fill some important gaps of knowledge in this field the Executive Body for the Convention on Long-range Transboundary Air Pollution decided to launch an international co-operative programme. The programme was started in September 1987 and has involved exposure at 39 test sites in 12 European countries and in the United States and Canada. The first phase of the exposure programme finished in 1995. However during the eight years where the exposure programme has been carried out, a large change in the pollution situation in Europe has been observed. In the final environmental data report for the period 1987 to 1995 (Henriksen et al., 1997), the same trend has been observed for most of the 39 test sites. The SO₂ concentrations have been drastically reduced while the change in the NO₂ and O₃ levels have been minor. This new pollution situation where the importance of NO₂ and O₃ were in focus, led to a proposal of a second phase of the programme. The new 4 years exposure project was launched in the fall 1997 with redefined environmental measuring programme, a better combination of test sites for field exposure and with several new countries as partners in the projects (Swedish Corrosion Institute rev. 1993). For the period 1995 to 1997 the on-going activities were; environmental measurements, exposure of polymeric and glass materials as well as trend analysis. The environmental data for this period and the first year in the second phase was reported last year (Henriksen and Arnesen, 2000)

The aim of the new programme is to perform a quantitative evaluation of the effect of NO_x and other pollutants like ozone and sulphur pollutants in combination with climatic parameters on the atmospheric corrosion of important materials. For this purpose, measurements of gaseous pollutants, precipitation and climate parameters have been initiated at or nearby each test site, together with corrosion evaluation of the exposed test materials at each site.

A Task Force is organising the programme with Sweden as lead country and Swedish Corrosion Institute serving as the Main Research Centre. Sub-centres in different countries have been appointed, each responsible for their own materials group. The materials groups are:

Structural metals:

- Steel and zinc for trend analyses (Sub-centre responsible for evaluation: SVUOM Praha a.s., Prague, Czech Republic),

- Zinc for 4 year's of exposure (EMPA Corrosion/Surface Protection, Dübendorf, Switzerland)
- Copper and cast bronze (Bayerisches Landesamt für Denkmalpflege, Munich, Germany).

Stone materials, Portland limestone (Building Research Establishment Ltd., Department of Environment, Waterford, United Kingdom).

Paint coatings, steel with silicon alkyd paint (Norwegian Institute for Air Research, Kjeller, Norway).

Glass materials, Two types of glass M1 and M3 (Institute of Chemistry, Academy of Fine Arts, Vienna, Austria)

Norwegian Institute for Air Research has been the sub-centre for the environmental database through the whole programme.

The exposure programme has fewer materials than in the first phase, mainly because we have to use materials, which is sensitive enough for having sufficient reaction within 4 years of exposure.

2 The measuring programme

The measuring programme includes a normal environmental programme and an extended programme, as shown in Table 1.

Table 1: The measuring programme

Components to be measured		
Normal programme	Gas Precipitation Climate	SO ₂ , O ₃ , NO ₂ mm, pH, SO ₄ -S, NO ₃ -N, Cl ⁻ , conductivity Temperature, relative humidity and sun radiation
Extended programme	Gas Precipitation Particulates	HNO ₃ NH ₄ -N, Na, Ca, Mg, K, Total amount

The data are to be reported to the environmental sub-centre as monthly mean values, except for sun radiation and mm precipitation, which are reported as the sums. The data are presented as monthly and yearly values for the project period.

3 Data from the monitoring test sites

The data are sent to the environmental sub-centre as excel data files on diskette or as E-mail.

All data presented by the environmental sub-centre are given with the same accuracy as in the reporting forms agreed upon. For data series which include

values "below the detection limit", these are, by convention, replaced with one half of the reported detection limits when calculating the mean values.

4 Monthly mean concentrations

The average monthly data reported is for November 1997 to October 1998 and November 1998 to October 1999 are given in Appendix B. The results from both the first and second year are reported since more data for the first year has been obtained since the previous report was finished. The participating countries are reporting data on a monthly base and are responsible for the quality control of their own data.

5 Calculation of monthly values

For their own test sites the participants shall calculate the mean values in accordance with the following equations.

- Mean temperature (T_M)

$$T_M = \frac{\sum_{i=1}^i T_i}{i}$$

T_i = measured values
 i = number of records

- Mean relative humidity (RH_M)

$$RH_M = \frac{\sum_{i=1}^i RH_i}{i}$$
- Sun radiation (sun) (for incomplete data sets

$$sh = \sum_{i=1}^i sh_i$$

see chapter 6.2)

If sunshine hours are reported as a substitute for sun radiation, sunshine hours shall report the number of hours where the test panels have been exposed to sunlight. A special designed program has been developed for transferring yearly values for sunshine hour to sun radiation.

- Mean gas concentrations G_M

$$G_M = \frac{\sum_{i=1}^i G_i}{i}$$

For some sites where complete information of the sampling period exists, another equation is used

$$G_M = \sum_{i=1}^i \frac{(n_i \cdot G_i)}{\sum_{i=1}^i n_i}$$

n_i = sampling period

- Precipitation (for incomplete data sets,
see chapter 6.2)

$$mm = \sum_1^i mm_i$$

- Weighted mean pH (pH_M)

$$pH_M = -\log \frac{\sum_1^i [mm_i \cdot (10^{-pH_i})]}{\sum_1^i mm_i}$$

- Weighted mean values for cations, anions and conductivity (C_M)

$$C_M = \frac{\sum_1^i (mm_i \cdot C_i)}{\sum_1^i mm_i}$$

6 Yearly mean concentrations

6.1 Yearly mean values

All values given for yearly mean values are calculated from the available monthly values. In Appendix A, the available yearly values for the two first years in the second phase of the programme are listed.

The calculation of the yearly values follows the procedure as for the monthly data. The quality of the yearly mean values depends on the amount of monthly values available. For the reported yearly values for gases and precipitation ions the following rules has been adopted:

- A yearly mean value for observations including 75% of the monthly values or more is accepted without any remarks
- A yearly mean value including between 50% and 75% of monthly data is accepted with an asterisk (*)
- A yearly value including less than 50% is reported with a (X) and is not recommended to be used for further statistical evaluations.

Temperature and relative humidity data will have seasonal variations and need a complete set of data. To complete the yearly results estimated values will be introduced in the same way as for sun radiation and amount of precipitation. See chapter 6.2

6.2 Sun radiation and amount of precipitation

Sun radiation and amount of precipitation are reported as the total sum and must be completed to a full year if the results shall be of any use. Since there are seasonal variations in the climatic factors the use of average values for adjusting the results can be incorrect. To complete the yearly results estimated values might be used. The estimated values can be formed by comparing similar sites, by

looking at reported values for other months from the same sites or from meteorological statistics. Only 4 estimated values are accepted for each parameter. If monthly values are available from the previous years, the missing monthly value is substituted with the mean value from the same month for the available years.

If more than 4 of the monthly values are missing no yearly value is reported.

7 Results

Environmental data for the ECE-ICP on materials programme has been collected since August 1987. From 1987 to 1995 data from 39 sites has been collected. For second exposure phase, the period 1997 to 2001, the programme was redefined and the number of sites with reporting data is now 31, since Poland has joined the programme. A list of all the test sites for phase one and two is given in Table 2. Based on the experience from the first phase of the programme the environmental parameters given in Table 1 were selected for the second phase. The main difference between data collected in the first and second phase is that Time of Wetness (TOW) should not be reported, that solar radiation should be reported instead of hours with sun and that ozone should be reported for all sites. It was also decided that all data should be reported to the environmental sub-centre as monthly values. The option of using passive samplers on a monthly base for measuring the gaseous pollutants was also introduced.

Optional particulates and HNO₃ can be reported in this phase of the programme. Particulates are reported for site 36 and 49 and HNO₃ for site 47. The data are reported in Appendix B.

For the analysis the environmental impact on material damages the environmental yearly mean values follow the exposure periods. The yearly mean values created are presented in Appendix A. In this report we are concentrating on the second phase of the exposure programme. The start of the second phase was for most test sites in October and November and for this phase the yearly values are calculated for the months November to October.

8 Model for computation of solar radiation

Some countries are still reporting the solar radiation as hours with sun. To convert these data into solar radiation a model for computation of solar radiation received by a horizontal surface at sea level has been developed. The model is based on the discrete ordinate solution to the radiative transfer equation (Stamnes et al., 1988) and is modified to include the curvature of the atmosphere (Dahlback and Stamnes, 1991). The model includes all orders of multiple scattering and absorption, and the ground is treated as a Lambertian reflector. The optical properties are allowed to vary vertically. The atmosphere is divided into a suitable number of layers to resolve the optical properties adequately. The model includes molecular (Rayleigh) scattering as well as scattering and absorption by clouds.

The solar radiation received by a horizontal surface, E, may be written as

$$E = \iint F(\tau_{eff}, O_3, Z, A, \lambda, \tau_R) \cdot d\lambda \cdot dt$$

where F is the spectral global irradiance (direct + diffuse radiation). The integration is performed over a time period of 1 year and the wavelength is integrated from 290 nm to 2900 nm in order to cover the complete solar spectrum. The spectral irradiance F depends on the cloud optical depth τ_c , the total ozone abundance, O_3 , the solar zenith angle, Z, the surface albedo, A, the wavelength, λ , and the Raleigh scattering optical depth, τ_R . The most important factors controlling the annual integrated solar energy, E, are the cloud cover and the solar zenith angle. Atmospheric ozone is included in the model but are assumed to be constant since variations in the ozone amount is of minor importance on the radiation integrated over the complete solar spectrum. The effect of aerosols in the lower troposphere may be of importance at some locations but are neglected here. The surface albedo, A, was set to 0.2 which is close a climatological mean value for continental vegetation (Kondratyev, 1969).

The model used in this work is designed to compute the surface solar radiation using the annual number of sunhours and latitude as input. The annual numbers of

sun hours are used to determine an effective cloud optical depth, τ_{eff} . The effective cloud optical depth is assumed in the calculations to be constant throughout the year and is determined by

$$\tau_{\text{eff}} = \left(\frac{(S_0 - S) \cdot \tau_c}{S} \right)$$

where S_0 is the maximal number of annual sun hours, S is the actual number of sun hours and τ_c is the cloud optical depth on a cloudy day. The present model is a modification of a radiation model used to determine cloud optical depth (Dahlback, 1996) from irradiance measurements with a multi channel filter instrument in Oslo, Norway. Measurements from this station in the period 1994-1996 are used to determine a typical optical depth on a cloudy day and found to be around 20. The time and latitude dependent solar zenith angle with 1 hour time-resolution is used in the calculations of the annual integrated solar radiation, E in MJ/m^2 .

9 Regularity and quality of the reported data

The test sites represent areas from background level of pollutant to urban and industry levels. The background sites have had the best regularity for the data reported. Many of these sites belong to the EMEP monitoring programme and had long and good data records.

In urban and industrial areas it is generally more difficult to maintain the site. In programmes like ECE/ICP materials with long exposure periods, it is sometime necessary to move a test site due to local problems like new use of the property. In some countries the funding of the environmental measurements was limited in the period between the end of the first exposure phase and the start of the second. This situation has become much better. However for some countries, the regularity for reporting the data has been slower than expected. This is illustrated as lack of data for some sites in Appendix A and B.

The solar radiation data reported the first year created some unexpected problems. We found large deviation between sites where the values were expected to be comparable and large deviation from earlier reported data. To investigate this problem, a questionnaire was sent out to all participants during the last year to get information about the instruments used, the calibration routines performed and the denomination used. The result of these questionnaires indicates that the main problem came from misunderstandings in the denominations. Some have reported daily mean values instead of monthly sums and some have used W/m^2 instead of MJ/m^2 . The values have now been corrected and the data is much better correlated in this report.

For data reported in W/m^2 the formulas for calculating the values in $\text{MJ/m}^2 \cdot \text{month}$ are:

Months with 31 days 1 $\text{W/m}^2 = 60 \times 60 \times 24 \times 31 / 1000000 = 2.678 \text{ MJ/m}^2 \cdot \text{month}$

Months with 30 days 1 $\text{W/m}^2 = 60 \times 60 \times 24 \times 30 / 1000000 = 2.592 \text{ MJ/m}^2 \cdot \text{month}$

Months with 28 days 1 $\text{W/m}^2 = 60 \times 60 \times 24 \times 28 / 1000000 = 2.419 \text{ MJ/m}^2 \cdot \text{month}$

Four sites are still reporting hours with sun instead of solar radiation. These results are recalculated in accordance with the model described in Chapter 8.

10 Evaluation of the data

10.1 The data distribution

It is important for the evaluation of the dose-response correlation for materials with the environmental impact that we have as large spread as possible in the concentrations of the most important pollution parameters. In the following figures the yearly mean values for the exposure year 1997-1998 for the most import parameters are given.

In Figure 1 and 2 the spread in the SO₂ concentrations for the first and second year is shown. The numbering is in accordance with the numbers in Table 2. The values go from 35 µg/m³ for Tel Aviv down to 0.2 µg/m³ at the Scandinavian EMEP stations for the first year. The distribution is fairly good. Low values are dominating in the base as expected since the total amount of sulphur emission in Europe has been reduced during the years of this program. The situation is similar for the second year except that site Tel Aviv had a much higher mean value. This is also illustrated in the scatterplot shown in Figure 7 in Chapter 10.2.

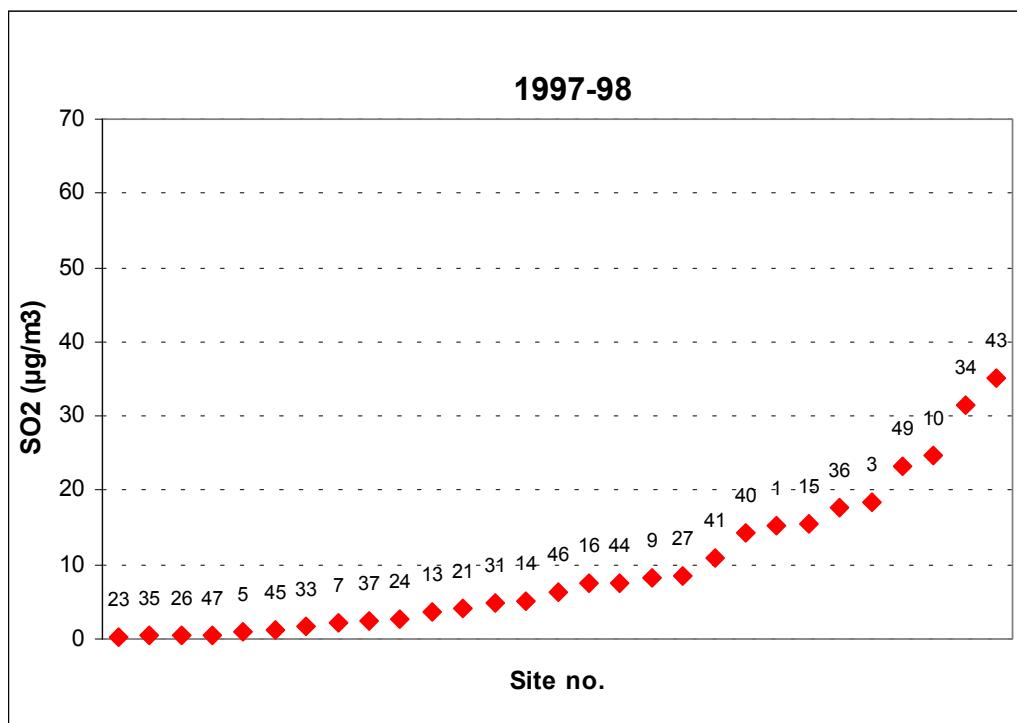

Figure 1: The spread in the yearly mean SO₂ concentrations at the test sites for the first year in phase 2 of the exposure programme.

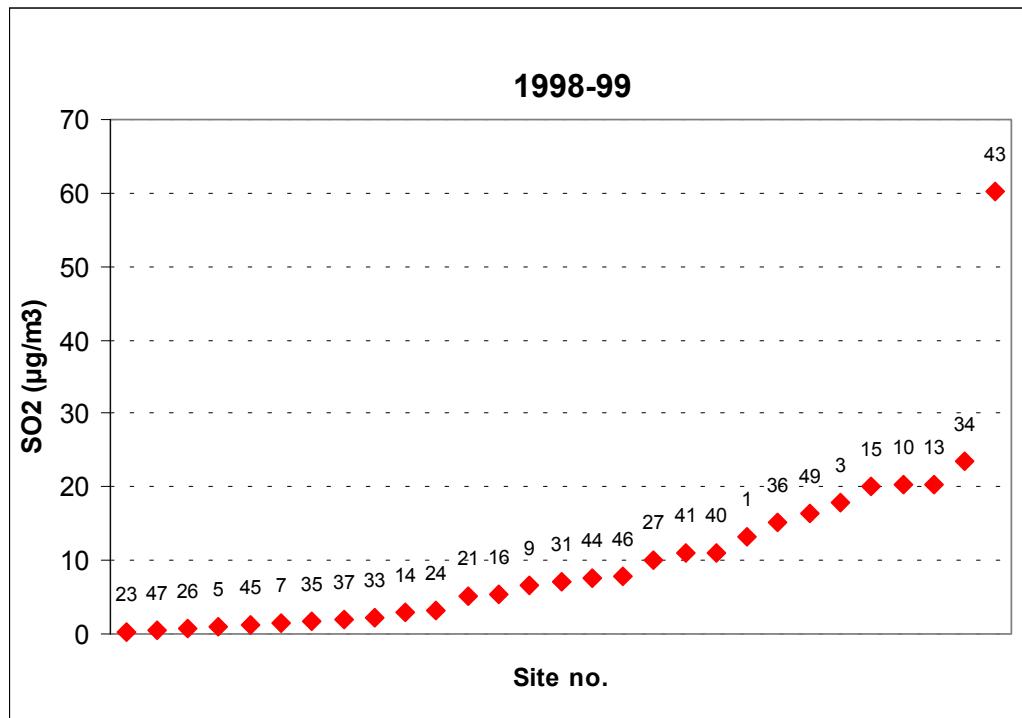

Figure 2: The spread in the yearly mean SO₂ concentrations at the test sites for the second year in phase 2 of the exposure programme

In Figure 3 and 4 the spread in the NO₂ concentrations for the first and second year is shown. The values go from 83 $\mu\text{g}/\text{m}^3$ for Milan down to 0.7 $\mu\text{g}/\text{m}^3$ at the EMEP station in Estonia for the first year. The distribution is fairly good. Low values are dominating in the base because of the number of EMEP sites in the programme. The distribution the second year was not so good. Some of the polluted sites had lower values except for Milan site 15.

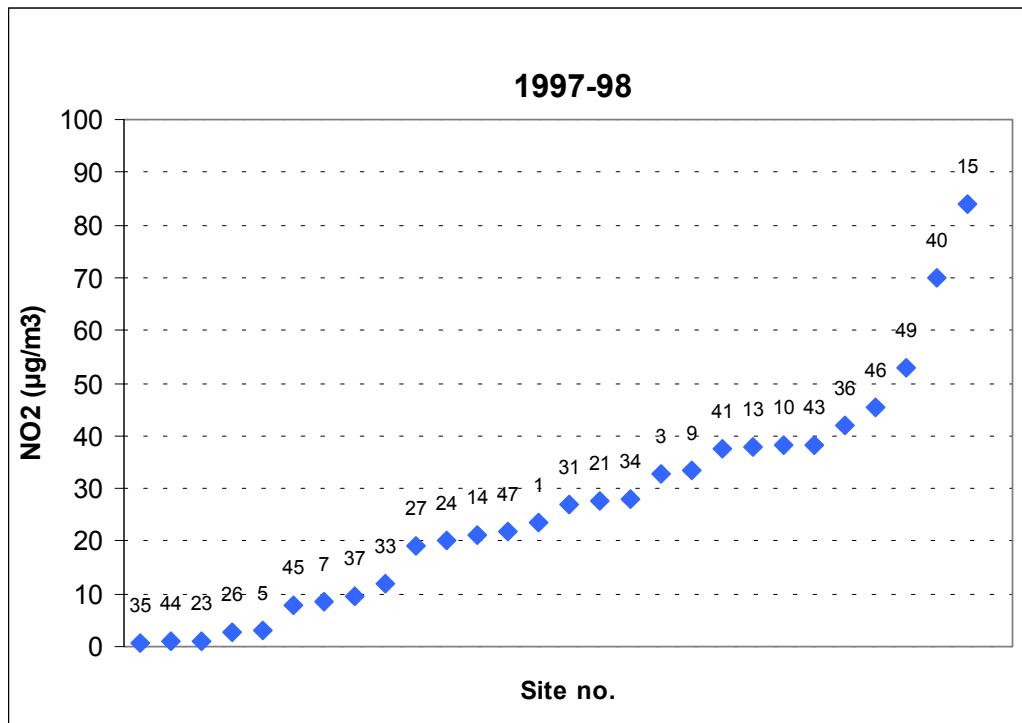

Figure 3: The spread in the yearly mean NO₂ concentrations at the test sites for the first year in phase 2 of the exposure programme.

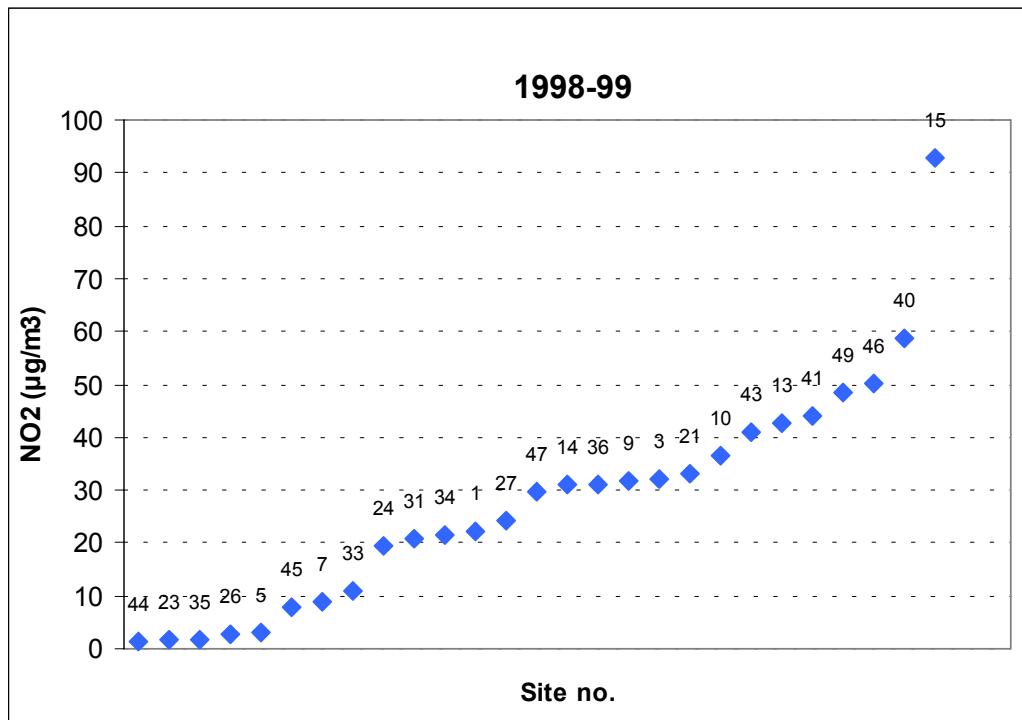

Figure 4: The spread in the yearly mean NO₂ concentrations at the test sites for the second year in phase 2 of the exposure programme.

In Figure 5 and Figure 6 the spread in the O₃ concentrations for the first and second year is shown. The values go from 88 µg/m³ for the EMEP station outside Toledo down to 21 µg/m³ in Berlin the first year. The distribution is as expected. It is a clustering of values around 50 µg/m³. The low values are observed in the big cities and high values in rural areas in the south and up in the alpine area. The situation is the same for the second year.

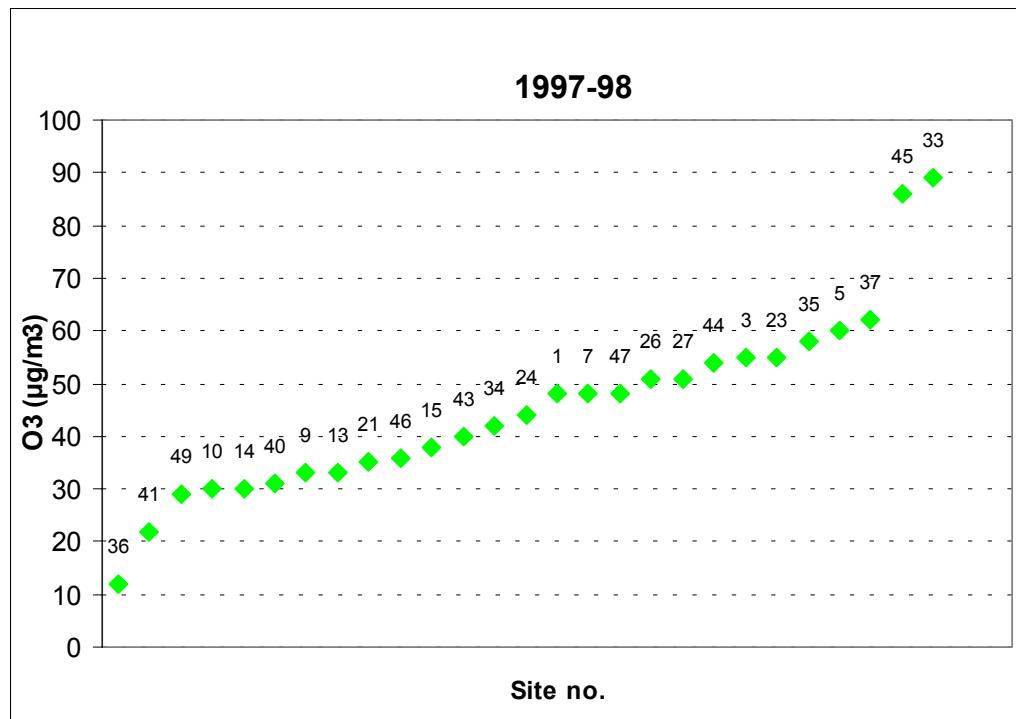

Figure 5: The spread in the yearly mean O₃ concentrations at the test sites for the first year in phase 2 of the exposure programme.

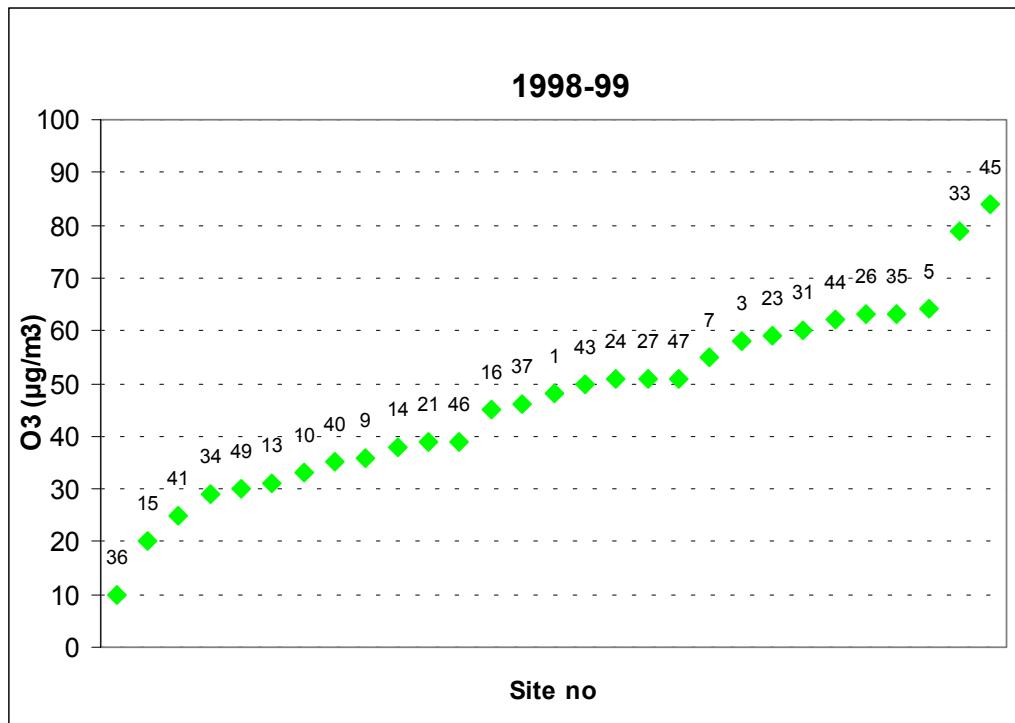

Figure 6: The spread in the yearly mean O₃ concentrations at the test sites for the second year in phase 2 of the exposure programme.

10.2 Trend analysis

During the time of the exposure programme some large changes have occurred in the pollution situation in Europe. In Report 34 (Henriksen and Arnesen, 2000) this was illustrated with scatter plots for some of the most important parameters like SO₂, NO₂ and O₃. The plots compared the data for 1987-88 with the data from 1997-98. The plots show a dramatic reduction in the SO₂ concentrations during the period. In average the reduction is close to 75% for SO₂, around 40% for NO₂ and no reduction for O₃. In this report we have checked if any change can be observed during the second phase of the programme. Scatter plots between the two first years of the programme has been made.

In Figure 7 a scatter plot of SO₂ for the two years 1997-98 and 1998-99 is shown. Most of the sites have comparable results for the two years. The largest deviation is observed for site 43 Tel Aviv, where the mean value for November 1997-October 1998 was 35 µg/m³ and the next year 60.3 µg/m³.

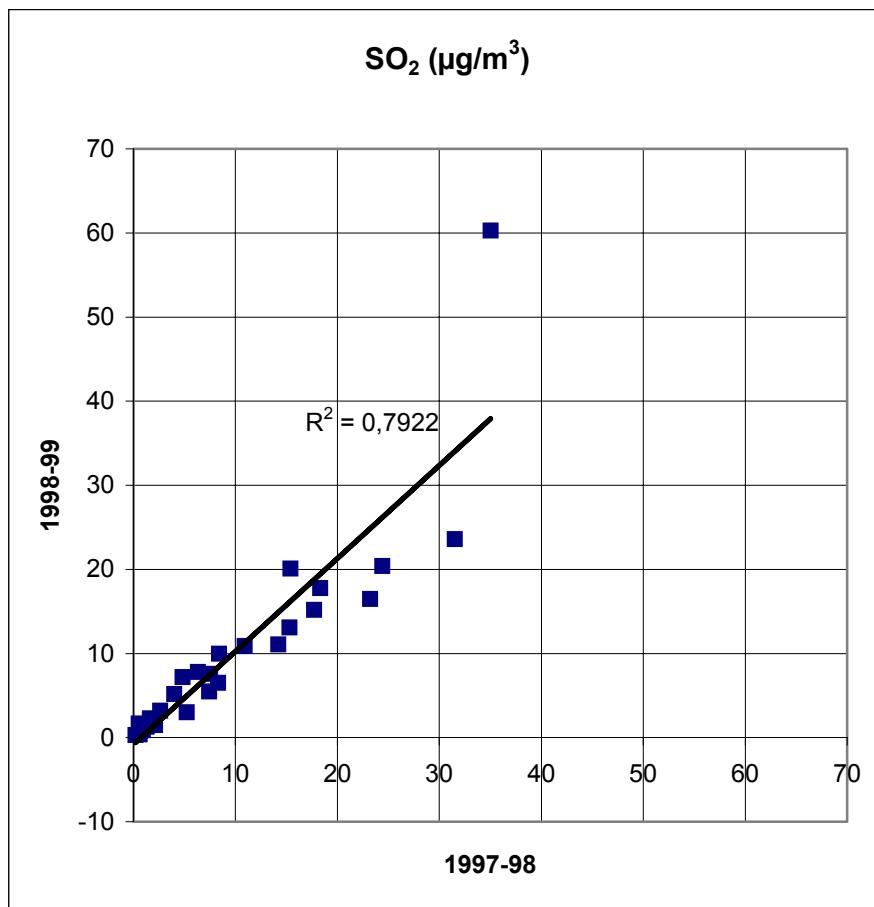

Figure 7: Scatterplot showing the change in the SO₂ concentrations for the same sites from 1997-98 to 1998-99.

The NO₂ values for the same two periods are shown in Figure 8. The plot shows that the NO₂ concentrations are comparable for the two years.

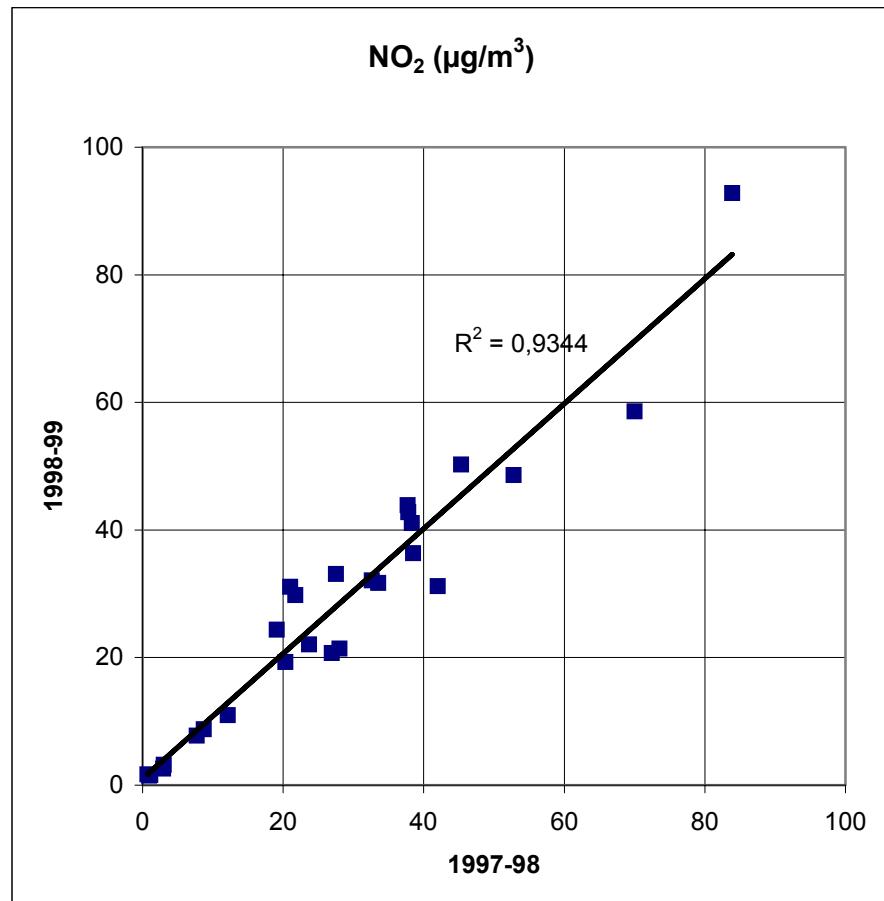

Figure 8: Scatterplot showing the change in the NO₂ concentrations for the same sites from 1997-98 to 1998-99.

Figure 9 shows the O_3 values for the same two periods. The plot shows small deviations in the O_3 levels between the two years.

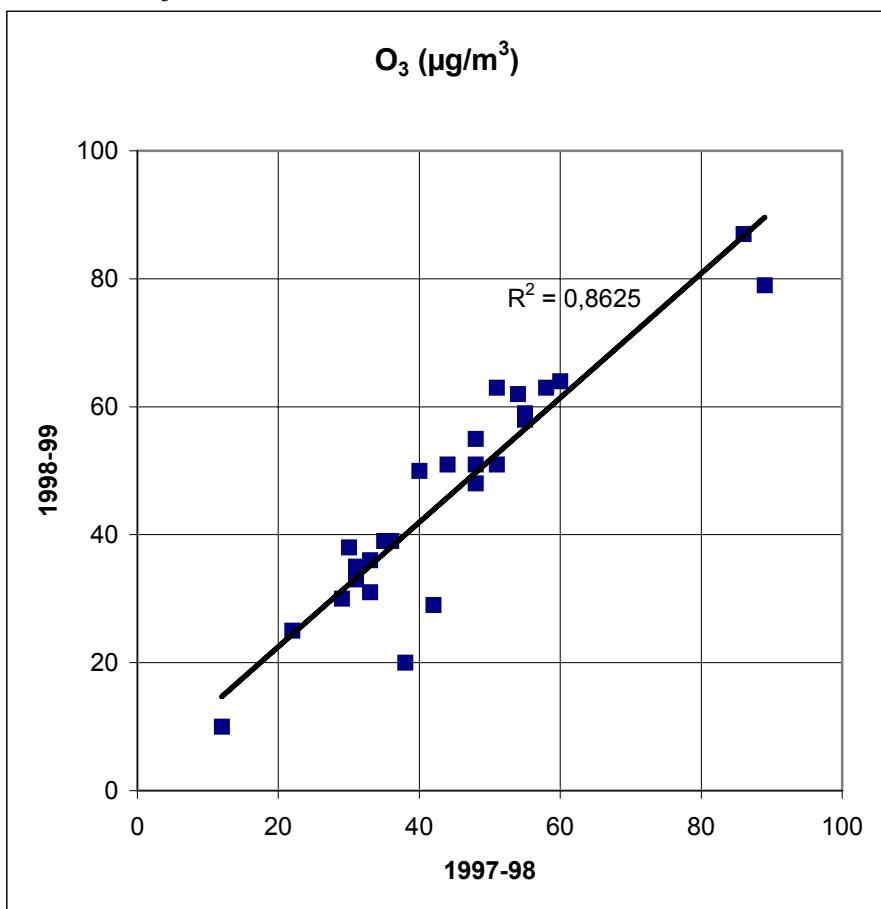

Figure 9: Scatterplot showing the change in the O_3 concentrations for the same sites from 1997-98 to 1998-99.

10.3 Solar radiation

In Figure 10 is the yearly sum for solar radiation given for all sites with data reported is shown. For some of the sites the values are reported without a final reconfirmation from the participating country. The sites are site 9, 10 47 and 49. Solar radiation data is not reported from site 34, 36 and 45 so far. By comparing the calculated data from sun hours with the data for solar radiation it looks like the calculation gives an underestimation of the real solar flux in the Mediterranean area. In the first phase of the programme the solar impact was reported as hours with sun. In chapter 8 a model for how sun hours can be recalculated into MJ/m² is described. For the sites where earlier data exist the mean values for the eight years have been introduced for comparison.

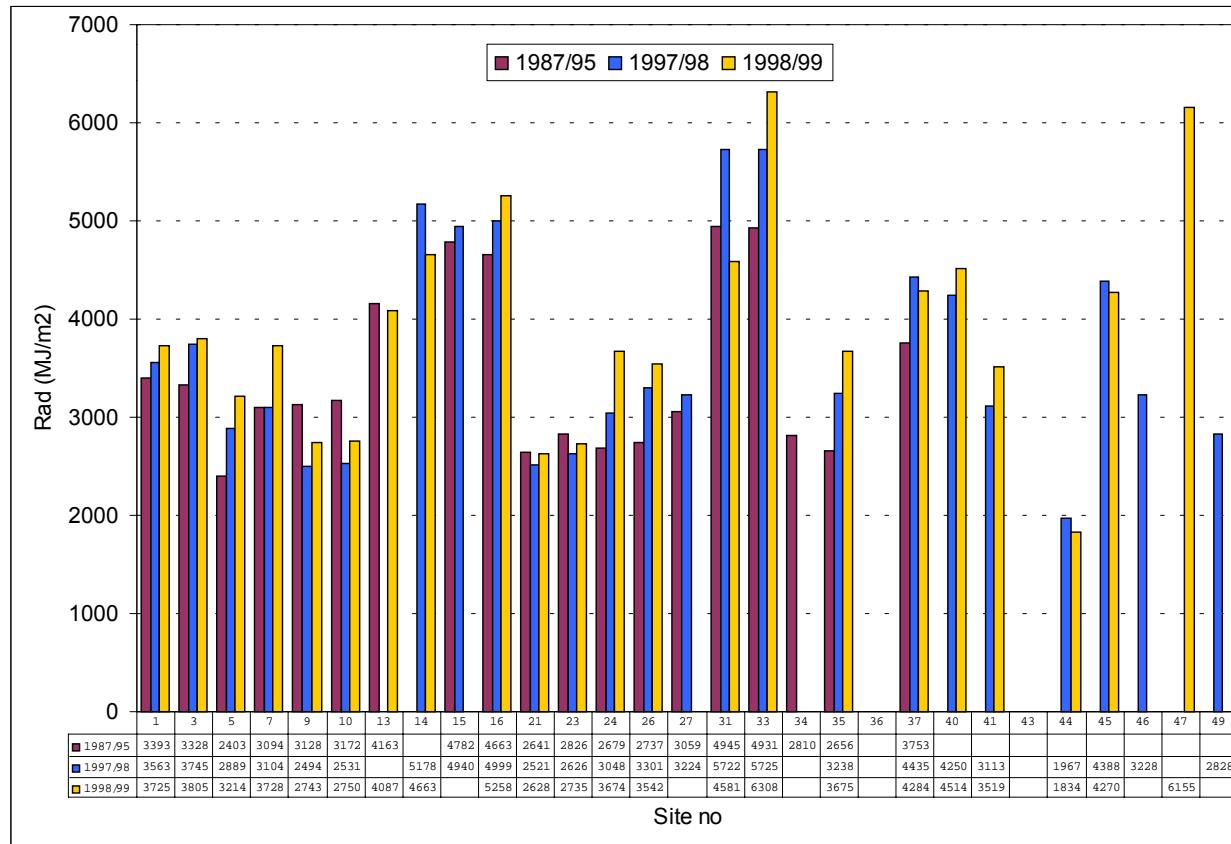

Figure 10: Yearly values for solar radiation for the sites for the first and second year of the second phase compared with the results from the mean value of the first phase.

REPORT SERIES Scientific Report	REPORT NO. OR 42/2001	ISBN 82-425-1288-4 ISSN 0807-7207			
DATE	SIGN.	NO. OF PAGES 70	PRICE NOK 125,-		
TITLE International Co-operative Programme on Materials, including Historic and Cultural Monuments		PROJECT LEADER Jan F. Henriksen			
Environmental data report November 1998 to October 1999		NILU PROJECT NO. O-8208			
AUTHOR(S) Jan F. Henriksen and Kari Arnesen		CLASSIFICATION * A			
		CONTRACT REF. SFT 990416			
REPORT PREPARED FOR Statens forurensningstilsyn P.O.Box 8100 Dep 0032 OSLO					
ABSTRACT This report presents the database for the second phase of the ECE ICP material programme. Besides presenting the available data for the two exposure years 1997/98 and 1998/99, the report presents the spread in the yearly mean values for the exposure sites.
